# 1 Introduction

Iris is a general-purpose, object-oriented programming language that combines features from Java, C, and C++. The language is class-oriented in that *almost* everything is a class. As such, it supports inheritance as well as other features like polymorphic, mutable lists, and encapsulation.

Iris introduces a spin on the normal conventions of encapsulation by introducing `permit` class members. These members are accessible by a class's sub-classes or other classes in its private collection of class names `permitted`. However, unlike *friend* classes in C++, a class's permitted classes may only access the `permit` methods of the class rather than all class methods.

## 1.1 Notation

Code is distinguished from prose by using this `font`.

# 2 Lexical Conventions

## 2.1 Comments

The characters `..` introduce a single-line comment.

The characters `.~*` introduce a multi-line comment, which terminates with `*~`.

## 2.2 Identifier Conventions

Any valid identifier in Iris is an uppercase or lowercase alphabetic character followed by any number of uppercase or lowercase alphabetic characters and/or digits. Uppercase and lowercase letters are distinct. The underscore `_` is also an alphabetic character.

## 2.3 Keywords

<code>if</code>	<code>public</code>	<code>bool</code>
<code>else</code>	<code>permit</code>	<code>char</code>
<code>for</code>	<code>permitted</code>	<code>string</code>
<code>while</code>	<code>private</code>	<code>float</code>
<code>return</code>	<code>void</code>	<code>List</code>
<code>class</code>	<code>univ</code>	<code>Olympus</code>
<code>new</code>	<code>const</code>	
<code>of</code>	<code>int</code>	

## 2.4 Literals

Iris allows for literals for each primitive data type:

### 2.4.1 Integer literals

An integer literal is any sequence of one or more digits. Integer literals can begin with exactly one `"-"`, and if so, are assumed to be negative. All integer literals are assumed to be in base 10.

### **2.4.2 Float literals**

A floating literal consists of 3 parts: a sequence of one or more digits, the decimal point, and another sequence of one or more digits. All 3 of these parts **MUST** be present for a float literal. Floating literals can optionally begin with exactly one `"-"`, and if so, are assumed to be negative. All float literals are assumed to be in base 10.

### **2.4.3 Boolean literals**

`true` and `false` are the only two boolean literals. These literals can be constructed from ASCII characters.

### **2.4.4 Character literals**

A character literal consists of one or two characters encapsulated in `'`. Inside the single quotes, there can be a single ASCII character, or one of the following special cases occurs: one of `'`, `n`, or `\` is preceded by a `\` to encode the single quote, newline, or backslash character, respectively.

### **2.4.5 String literals**

A string literal consists of a series of character literals surrounded by double quotes. Within the string literal, a `"` character must be preceded by a single `\`.

## **3 What's In a Name?**

optional univ, datatype, identifier,

## **4 Types**

### **4.1 Operators**

## **5 Expressions**

## **6 Classes**

### **6.1 Encapsulation**

### **6.2 Inheritance**

## **7 Built-In Functions**

### **7.1 Lists**

### **7.2 The Olympus Class**

## **8 Scope**
